

Docker volume

Docker volumes in docker are used to persist data outside containers.

Without the volumes:

- Container data disappears when the container is deleted

With volumes:

- Data survives container restarts and deletions

So

- You run a database container
 - Store data inside it
 - Delete the container
- > Without a volume: all database is lost

Create a volume

```
docker volume create {myvolume}
```

Check volume

```
docker volume ls
```

Use volume in a container

```
docker run -it \-v {container}:/app/data \ubuntu bash
```

- /app/data = Path inside container
