

```
if __name__ == "__main__":
```

```
    if __name__ == "__main__":
```

--> Only run this code when the file is executed directly.

So, basically, imagine that we have a file named `app.py` that have the `if __name__ == "__main__":`

and if we execute the `python app.py` directly, so the condition becomes true.

And if the file is imported

```
import app
```

then inside the `app.py`:

```
__name__ == "app"
```

So the condition is false.]

Purpose: This prevent certain code from running automatically during the import

Example:

```
`def add(a, b):
```

```
    return a + b
```

```
if name == "main":
```

```
    print(add(2, 3))`
```
