

Inferencing

There are two main types of inferencing in ML

- batch inferencing
- real-time inferencing

Batch inferencing is when the computer takes a large amount of data, such as images or text, and analyzes it all at once to provide a set of results.

This type of inferencing is often used for tasks like data analysis, where the speed of the decision-making process is not as crucial as the accuracy of the results.

Real-time inferencing is when the computer has to make decisions quickly, in response to new information as it comes in.

This is important for applications where immediate decision-making is critical, such as in chatbots or self-driving cars. The computer has to process the incoming data and make a decision almost instantaneously, without taking the time to analyze a large dataset.
